Technical features / Advantages

FEMR

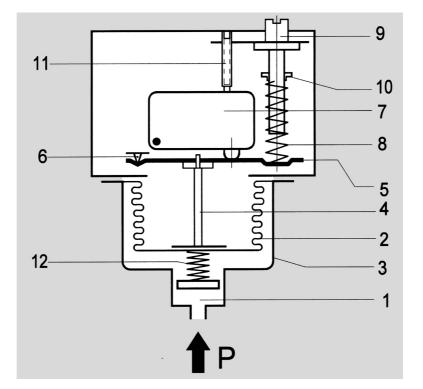

# **Pressure switches**

# General description

# **Operating mode**

The pressure occurring in the sensor housing (1) acts on the measuring bellows (2). Changes in pressure lead to movements of the measuring bellows (2) which are transmitted via a thrust pin (4) to the connecting bridge (5). The connecting bridge is frictionlessly mounted on hardened points (6). When the pressure rises the connecting bridge (5) moves upwards and operates the microswitch (7). A counterforce is provided by the spring (8) whose pretension can be modified by the adjusting screw (9) (switching point adjustment). Turning the setting spindle (9) moves the running nut (10) and modifies the pretension of the spring (8). The screw (11) is used to calibrate the microswitch in the factory. The counter-pressure spring (12) ensures stable switching behaviour, even at low setting values.

- **1** = Pressure connection

#### **Pressure sensors**

Apart from a few exceptions in the low-pressure range, all pressure sensors have measuring bellows, some made of copper alloy, but the majority of high-quality stainless steel. Measured on the basis of permitted values, the measuring bellows are exposed to a minimal load and perform only a small lifting movement. This results in a long service life with little switching point drift and high operating reliability. Furthermore, the stroke of the bellows is limited by an internal stop so that the forces resulting from the overpressure cannot be transmitted to the switching device. The parts of the sensor in contact with the medium are welded together without filler metals. The sensors contain no seals. Copper bellows, which are used only for low pressure ranges, are soldered to the sensor housing. The sensor housing and all parts of the sensor in contact with the medium can also be made entirely from stainless steel 1.4571 (DNS series). Precise material data can be found in the individual data sheets.

### Pressure connection

The pressure connection on all pressure switches is executed in accordance with DIN 16288 (pressure gauge connection G 1/2A). If desired, the connection can also be made with a G 1/4 internal thread according to ISO 228 Part 1. Maximum screw-in depth on the G 1/4 internal thread = 9 mm.

## Centring pin

In the case of connection to the G 1/2 external thread with seal in the thread (i.e. without the usual sheet gasket on the pressure gauge connection), the accompanying centring pin is not needed. Differential pressure switches have 2 pressure connections (max. and min.) each of which are connected to a G 1/4 internal thread.

# Setting instructions

# Factory calibration of pressure switches

In view of tolerances in the characteristics of sensors and springs, and due to friction in the switching kinematics, slight discrepancies between the setting value and the switching point are unavoidable. The pressure switches are therefore calibrated in the factory in such a way that the setpoint adjustment and the actual switching pressure correspond as closely as possible in the middle of the range. Possible deviations spread to both sides equally.

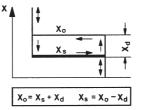

The device is calibrated either for falling pressure (calibration at lower switching point) or for rising pressure (calibration at higher switching point), depending on the principal application of the type series in question.

Where the pressure switch is used at other than the basic calibration, the actual switching point moves relative to the set switching point by the value of the average switching differential. As FEMA pressure switches have very small switching differentials, the customer can ignore this where the switching pressure is set only roughly. If a very precise switching point is needed, this must be calibrated and checked in accordance with normal practice using a pressure gauge.

# 1. Calibration at lower switching point

Setpoint  $x_s$  corresponds to the lower switching point, the upper switching point  $x_o$ is higher by the amount of the switching differential  $x_d$ . **2. Calibration at upper switching point** Setpoint x<sub>s</sub> corresponds to the upper

switching point, the lower switching point  $x_0$  is lower by the amount of the switching differential  $x_d$ .

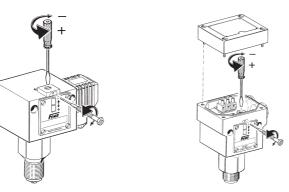

The chosen calibration type is indicated in the technical data for the relevant type series.

# Setting switching pressures

Prior to adjustment, the securing pin above the scale must be loosened by not more than 2 turns and retightened after setting. The switching pressure is set via the spindle. The set switching pressure is shown by the scale.

To set the switching points accurately it is necessary to use a pressure gauge.

Clockwise: greater difference Anticlockwise: smaller difference

With pressure switches of the DWAMV and DWR...-203 series, the direction of action of the differential screw is reversed.

# Changing the switching differential (only for switching device with suffix "V", ZF 203)

By means of setscrew within the spindle. The lower switching point is not changed by the differential adjustment; only the upper switching point is shifted by the differential. One turn of the differential screw changes the switching differential by about of the total differential range. The switching differential is the hysteresis, i.e. the difference in pressure between the switching point and the reset point.

# Lead seal of setting spindle (for plug connection housing 200 only)

The setting spindle for setting the desired value and switching differential can be covered and sealed with sealing parts available as accessories (type designation: P2) consisting of a seal plate and capstan screw. The sealing parts may be fitted subsequently. The painted calibration screws are likewise covered.

Clockwise: lower switching pressure

> Anticlockwise: higher switching pressure

Direction of action of setting spindle

# Explanation of type designations - type codes

The type designations of FEMA pressure switches consist of a combination of letters followed by a number denoting the setting range. Additional functions and version variants are indicated by a code which is separated from the basic type by a hyphen. Ex versions (explosion protection EEx-d) are identified by the prefix "Ex" in front of the type designation.

	version	with additional function	Ex-version

Pressure switches with 2 microswitches - technical data

FEMA pressure switches of the **DCM** (except DCM 1000, DCM 4016 and DCM 4025), **VCM** (except VCM 4156), **VNM, DNS, VNS** series and the differential pressure monitor **DDCM** (except DDCM 252, 662, 1602, 6002) can be

equipped with 2 microswitches (see also the table on page 41). This is not possible with any other type series or with Ex versions.

#### **Technical data**

#### Standard equipment

The standard equipment of every two-stage pressure switch includes a switching device with 2 microswitches, both single-pole switching. Switch I monitors the low pressure, switch I the higher pressure. The setting ranges indicated in the data sheets for the basic types apply to the two-stage pressure switches as well. It should be noted that the switching differentials of the individual microswitches may not be exactly the same due to component tolerances.

#### Switching interval

The switching interval of the two microswitches is the difference (in bar or mbar) between the switching points of the two microswitches.

#### For example:

When the pressure rises, a two-stage pressure switch turns on a warning light (e.g. 2.8 bar), and if the pressure continues to rise (e.g. 3.2 bar) the system shuts down. The switching interval is 3.2-2.8 = 0.4 bar. For all versions the rule is:

The switching interval remains constant over the whole setting range of the pressure switch. If the switching pressure setting is changed with the setting spindle, the switching interval does not change – the switching points are moved in parallel.

#### Switching differential

The switching differential, i.e. the hysteresis of the individual microswitches, corresponds to the values of the relevant basic design referred to in the Product Summary. In the case of twostage pressure switches, **the switching differential of the individual microswitches is not adjustable**.

#### Versions

Two-stage pressure switches are available in three different versions, each identified by a ZF number. The versions differ in terms of their connection schemes and electrical connection types (terminal or plug connection).

The applicable data sheet for the basic types contains the technical data for the two-stage pressure switches. This includes all limits of use, temperature, maximum pressure, mounting position, type of protection, electrical data etc. The principal dimensions are the same as for single-stage pressure switches, with similar pressure ranges and design features.

# Switching intervals of two-stage pressure switches (ZF 217, ZF 307)

# Switching devices with adjustable switching interval

# Additional function ZF 217

On switching devices with additional function ZF 217, the switching interval is continuously adjustable via two adjustment knobs I and II accessible from outside. The maximum switching intervals are stated in the "Switching intervals" table.

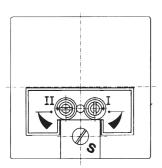

Turning adjustment knob I clockwise produces a lower switching point for microswitch I. Turning adjustment knob II anticlockwise produces a higher switching point for microswitch II. Adjustment knobs I and II have an internal stop to prevent the microswitches from being adjusted beyond the effective range.

Adding together the adjustments on knobs I and II gives the switching interval between the two microswitches. Changes made with the setting spindle do not affect the switching interval. The switching interval remains constant over the whole setting range of the spindle. The two switching points are moved up or down in parallel.

## Recommended adjustment method for switching devices with ZF 217

- 1. Set adjustment knobs I and II to their basic positions.

  - Turn adjustment knob I Turn adjustment knob II
- as far as possible anticlockwise.
- as far as possible clockwise.
- 2. Adjust the setting spindle S by the scale to a value midway between the desired upper and lower switching points.
- 3. With pressure applied, set the lower switching point with adjustment knob I.
- 4. In the same way as in step 3, set the upper switching point with adjustment knob II.
- 5. If the desired upper and lower switching points cannot be reached, turn the setting spindle S in the appropriate direction and repeat steps 3 and 4.

# S2 type series

# Two-stage pressure switches, switching schemes for ZF 217

Function-appropriate internal configuration of microswitches I and II, switching scheme selection table. The switch position shown corresponds to the pressureless state. On the horizontal axis is the switching function of microswitch I (A-D); on the vertical axis is the switching function of microswitch II (1-4). At the intersection is the switching scheme which satisfies both conditions (e.g. A 2).

## Information required when ordering:

As well as the basic type (e.g. DCM 10) and the switching scheme (e.g. A 2), for factory setting it is also necessary to indicate the switching points and direction of action:

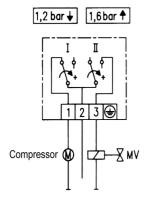

Example: DCM 10-217 / A 2 Switch I: 6.5 bar falling, Switch II: 7.5 bar rising.

# S2 type series

# Examples of use for two-stage pressure switches

Pressure monitoring and controlling can be greatly simplified by using pressure monitors with two built-in microswitches which can be made to operate one after the other under rising or falling pressure. For example, minimum and maximum pressure monitoring can be achieved with only **one** pressure switch, doing away with the need for a second pressure switch (including the cost of installation). Step switching, e.g. pressure-dependent control of a two-stage pump, is of course also possible using this special series.

## For pressure-dependent control of automatic expansion valves and pressure holding devices

# Example 1:

## Requirement

Pressure holding devices and automatic expansion valves usually have a gas cushion whose pressure must be kept constant within a certain range. If the pressure is too low, a compressor is switched on. If the pressure is too high, a solenoid valve must be opened to vent the gas. Between these two levels is a neutral zone, in which the compressor and the solenoid valve are at rest.

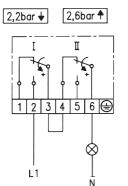

## Solution

All pressure switches of types DCM, DNM, DNS, each with additional function ZF 217 and switching scheme A 2, are suitable. All pressureranges listed in the technical documents are possible. Example for ordering: DCM 6-217/A 2

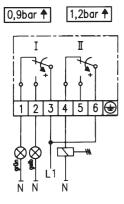

### Switching function / connection scheme

Switch I:	With falling pressure, contact 1–2 closes (compressor on) With rising pressure, contact 1–2 opens (compressor off)
Switch II:	With rising pressure, contact 2–3 closes (valve open) With falling pressure, contact 2 –3 opens (valve closed). In between there is a neutral zone in which the compressor is not switched on and the solenoid coil is not energized (off position).

## Minimum and maximum pressure monitoring in a nitrogen line

Filter monitoring with a 2-stage differential pressure switch

# Example 2: Requirement

In a process engineering system, the pressure in a nitrogen line has to be monitored. A green signal lamp indicates that the pressure in the line is between 2.2 and 2.6 bar. If the pressure goes below 2.2 bar or above 2.6 bar, the indicator lamp goes out and the system shuts down.

## Solution

The first contact of a DCM 3–307 pressure switch with 2 microswitches opens under falling pressure at 2.2 bar; the second microswitch opens under rising pressure at 2.6 bar. If the pressure is >2.2 bar and <2.6 bar, the circuit is closed via both microswitches and the signal lamp is lit.

# Example 3:

# Requirement

The gradual fouling of a filter system is to be monitored by a differential pressure switch. Increased fouling causes a higher differential pressure between the input and the output of the filter system. A green signal lamp indicates the normal operating state. If fouling reaches a certain value (differential pressure >0.9 bar), a yellow signal lamp warns the operator that it is time to change the filter elements. If this is not done and the differential pressure rises due to further fouling (e.g. to >1.2 bar), the system must be shut down.

## Solution

A differential pressure switch DDCM 6–307 operates under rising differential pressure (at 0.9 bar), the green control lamp goes out; at the same time the yellow lamp comes on (warning that it is time to clean the filter). If the differential pressure continues to rise (to >1.2 bar), the circuit opens via 4–6 of the second microswitch, the relay drops out and the system shuts down.

# VCM type series

# Negative pressure switches (vacuum switches)

FEMA negative pressure switches detect the pressure difference relative to atmospheric pressure. All data relating to the setting range and thus also the scale divisions on the switching devices are to be understood as the difference in pressure between the relevant atmospheric pressure and the set switching pressure.

drawing

#### **Technical data**

#### Pressure connection

External thread G 1/2 (pressure gauge connection) according to DIN 16 288 and internal thread G 1/4 according to ISO 228 Part 1.

#### Switching device

Robust housing (200) made of seawaterresistant diecast aluminium GD Al Si 12.

#### **Degree of protection**

IP 54, in vertical position IP 65. for EEx-d version

#### Pressure sensor materials

VNIVI 111 and	Metal bellows: 1.4571
VNM 301:	Sensor housing: 1.4104
VCM 095, 101	Metal bellows of Cu Zn
and 301:	Sensor housing of CuZn
VCM 4156:	Perbunan diaphragm sen-
	sor housing: 1.4301

#### Mounting position

Vertically upright and horizontal VCM 4156 vertically upright.

#### Ambient temp. at switching device –25…+70 °C

For EEx-d versions: -15...+60 °C

# Max. medium temperature

The maximum medium temperature at the pressure sensor must not exceed the permitted ambient temperature at the switching device. Temperatures may reach 85°C for short periods (not EEx-d). Higher medium temperatures are possible provided the above limit values for the switching device are ensured by suitable measures (e.g. siphon).

# Mounting

Directly on the pressure line (pressure gaugeconnection) or on a flat surface with two 4 mm Ø screws.

# Switching pressure Adjustable from outside with screwdriver.

Switching differential

Not adjustable with VCM and Ex-VCM types. Adjustable with VCM-203 type. For values see Product Summary.

\* At very high vacuums, close to the theoretical maximum of -1 bar, the switch may not be usable in view of the special conditions of vacuum engineering. However, the pressure switch itself will not be damaged at maximum vacuum.

For additional functions refer to ZF data sheet. For smaller pressure ranges see also HCD and DPS data sheets.

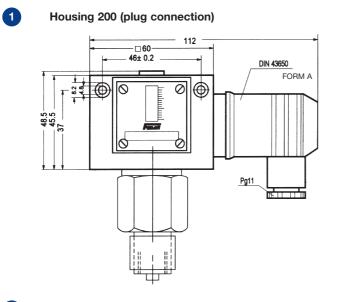

## Calibration

The VCM and VNM series are calibrated for falling pressure. This means that the adjustable switching pressure on the scale corresponds to the switching point at falling pressure. The reset point is higher by the amount of the switching differential. (See also page 30, 1. Calibration at lower switching point).
